The force that holds atoms together in a covalent bond is the attraction of each atom's nucleus for the shared pair of electrons. Chapter 5 Atoms and Bonding How Covalent Bonds Form The oxygen atom in water and the nitrogen atom in ammonia each have eight valence electrons as a result of forming covalent bonds with hydrogen atoms.

Atoms And Bonding Study Guide The number and arrangement of electrons of an atom determine the kinds of chemical bonds that it forms and how it reacts with other atoms to form molecules. There are three kinds of chemical bonds: Ionic bonds form between two atoms when one or more electrons are completely transferred from one atom to the other.

The properties of solid metals can be explained by the structure of metal atoms and the bonding between those atoms. Recall that most metals have one, two, or three valence electrons. When metal atoms combine chemically with atoms of other elements, they usually lose valence electrons. As a result, they become positively charged ions.

A polar bond is a covalent bond in which atoms share electrons unequally. The atom that pulls the electrons more strongly gain a slight negative charge, while the atom that is "weaker" gains a slight positive charge. On the other hand, a nonpolar bond is a covalent bond in which atoms share electrons equally.
