can cause difficulties to estimate correctly the load effects on the fatigue strength of structure components. In the case of large steel structures with complex details, such as welded joint components in orthotropic bridge decks, an accurate estimation of the load effects in its welded details is often difficult to obtain applying a global life

In the current study a method to determine the location of fracture initiation for non-load carrying fillet welds based on continuous geometry measurements is proposed. Measurements and weld quality evaluation were carried out on welded specimens using the Wintertia® software qWeld. One hundred nineteen specimens were produced, scanned, and fatigue tested until failure.

The advantages of welding are numerous over that of mechanical linkages; however, the fatigue life of a welded component can be significantly reduced over that of un-welded component made of the same steel. Figure 4 shows a comparison of the S-N fatigue life of an un-welded member, a stress raising notch and a fillet welded component.

A welded structure may not have greater fatigue resistance than an unwelded plate so this represents an upper bound on the fatigue behaviour. The curves are straight lines, on a log-log scale. Below 107cycles the slope of these lines is 3, the same slope that is found in crack growth data.
